  IntLiteral ( n ) then  
    li $a0 n
```

Con  
run-t

to be a bit sloppy about the datatype  
instructions.

Assignment Project Exam Help

<https://eduassistpro.github.io>

Add WeChat edu\_assist\_pr

## Code generation: integer literals

Let's start with the simplest case.

```
def genExp ( e : Exp ) =  
  if e.isIntForm  
  then IntLiteral ( n ) then  
    li $a0 n
```

Con  
run-t

to be a bit sloppy about the datatype  
instructions.

This preserves all invariants to do with the sta  
accumulator as required. Recall that `li` is a pseudo instruction  
and will be expanded by the assembler into several real MIPS  
instructions.

## Code generation: addition

```
def genExp ( e : Exp ) =  
  if e is of form  
    Add ( l, r ) then  
    genExp ( l )  
    sw $a0 0($sp)  
    addiu $sp $sp -4
```

Assignment Project Exam Help

<https://eduassistpro.github.io>

```
addiu $sp $sp 4
```

Note that this evaluates from left to right! Recall that the stack grows downwards and that the stack pointer points to the first free memory cell above the stack.

Add WeChat edu\_assist\_pro

## Code generation: addition

```
def genExp ( e : Exp ) =  
  if e is of form  
    Add ( l, r ) then  
    genExp ( l )  
    sw $a0 0($sp)  
    addiu $sp $sp -4
```

Assignment Project Exam Help

<https://eduassistpro.github.io>

```
addiu $sp $sp 4
```

Note that this evaluates from left to right! Recall that the stack grows downwards and that the stack pointer points to the first free memory cell above the stack.

Question: Why not store the result of compiling the left argument directly in \$t0?

## Code generation: addition

```
def genExp ( e : Exp ) =  
  if e is of form  
    Add ( l, r ) then  
    genExp ( l )  
    sw $a0 0($sp)  
    addiu $sp $sp -4
```

Assignment Project Exam Help

<https://eduassistpro.github.io>

```
addiu $sp $sp 4
```

Note that this evaluates from left to right! Recall that the stack grows downwards and that the stack pointer points to the first free memory cell above the stack.

Question: Why not store the result of compiling the left argument directly in `$t0`? Consider `1+(2+3)`

Code generation: minus

# Assignment Project Exam Help

We want to translate  $e - e'$ . We need new MIPS command:

<https://eduassistpro.github.io>

It subtracts  $r_2$  from  $r_1$  and stores the result in  $reg1$ . I.e.  $reg1 := r_1 - r_2$

Add WeChat edu\_assist\_pro

Code generation: minus

# Assignment Project Exam Help

```
def genExp ( e : Expr ) =  
  if e is of form  
    Minus ( l, r ) then
```

<https://eduassistpro.github.io>

```
    lw $t1 4($sp)
```

```
    sub $a0 $t1 $a0 // only change from a
```

```
    addu $sp $sp 4
```

# Add WeChat edu\_assist\_pro

Note that `sub $a0 $t1 $a0` deducts \$a0 from \$t1.

## Code generation: conditional

We want to translate `if  $e_1 = e_2$  then  $e$  else  $e'$` . We need two new MIPS commands:

```
beq reg1 reg2 label
```

<https://eduassistpro.github.io>

`beq` branches (= jumps) to `label` if the content of `reg1` is identical to the content of `reg2`. Otherwise moves on to the next command.

## Code generation: conditional

We want to translate `if  $e_1 = e_2$  then  $e$  else  $e'$` . We need two new MIPS commands:

```
beq reg1 reg2 label
```

<https://eduassistpro.github.io>

`beq` branches (= jumps) to `label` if the contents of `reg1` and `reg2` are identical. Otherwise, the processor moves on to the next command.

In contrast `b` makes an unconditional jump to `label`.

## Code generation: conditional

```
def genExp ( e : Exp ) =  
  if e is of form  
    If ( l, r, thenBody, elseBody ) then  
      val elseBranch = newLabel () // not needed  
      val thenBranch = newLabel ()  
      val exitLabel = newLabel ()
```

<https://eduassistpro.github.io>

```
    lw $t1 4($sp)  
    addiu $sp $sp 4  
    beq $a0 $t1 thenBranch  
    elseBranch + ":"  
    genExp ( elseBody )  
    b exitLabel  
  thenBranch + ":"  
    genExp ( thenBody )  
  exitLabel + ":" }
```

## Code generation: conditional

```
def genExp ( e : Exp ) =  
  if e is of form  
    If ( l, r, thenBody, elseBody ) then  
      val elseBranch = newLabel () // not needed  
      val thenBranch = newLabel ()  
      val exitLabel = newLabel ()
```

<https://eduassistpro.github.io>

```
    lw $t1 4($sp)  
    addiu $sp $sp 4  
    beq $a0 $t1 thenBranch  
    elseBranch + ":"  
    genExp ( elseBody )  
    b exitLabel  
  thenBranch + ":"  
    genExp ( thenBody )  
  exitLabel + ":" }
```

`newLabel` returns new, distinct string every time it is called.

Code generation: procedure calls/declarations

The code a compiler emits for procedure calls and declarations depends on the layout of the activation record (AR).

The result is always in the accumulator, so no need for to store the result in the AR.

The o

We h

pus

st

<https://eduassistpro.github.io>

The AR needs to store the return address.

The stack calling discipline ensures that on p is the same as on procedure entry.

Also: no registers need to be preserved in accumulator machines. Why? Because no register is used except for the accumulator and `$t0`, and when a procedure is invoked, all previous evaluations of expressions are already discharged or 'tucked away' on the stack.

## Code generation: procedure calls/declarations

So ARs for a procedure with  $n$  arguments look like this:

caller's FP
argument $n$
...
arg
ret

A pointer (whose memory address sits) is useful (though not necessarily a pointer) is called **frame pointer** and live in the AR upon procedure entry. The FP makes variables easier (see later).

## Code generation: procedure calls/declarations

So ARs for a procedure with  $n$  arguments look like this:

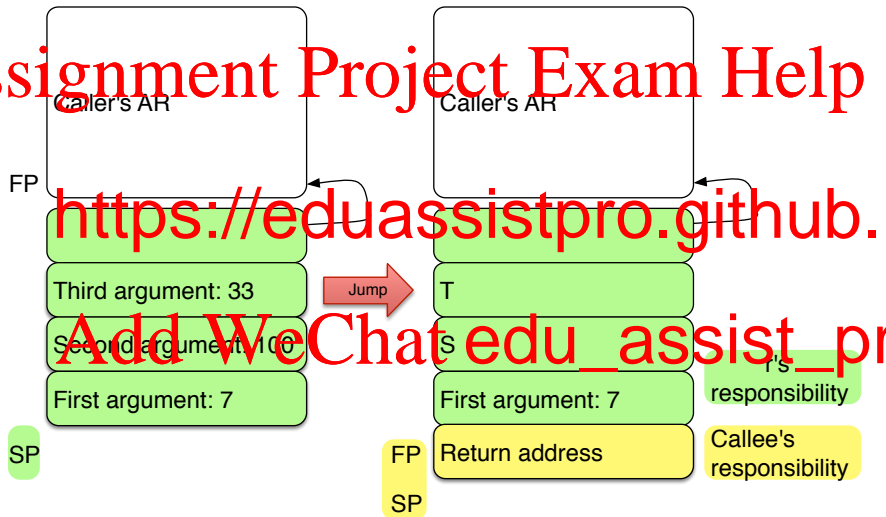

caller's FP
argument $n$
...
arg
ret

A pointer (whose memory address sits) is useful (though not necessarily a pointer is called **frame pointer** and live need to restore the caller's FP or procedure e in the AR upon procedure entry. The FP make variables easier (see later).

Arguments are stored in reverse order to make indexing a bit easier.

# Code generation: procedure calls/declarations

Let's look at an example: assume we call  $f(7, 100, 33)$

## Code generation: frame pointer

Variables are just the procedure parameters in this language.

They are all on the stack in the AR, pushed by the caller. How do we access them? The obvious solution (use the SP with appropriate offset) does not work (at least not easily).

Prob

resu

so th

in

<https://eduassistpro.github.io>

```
def f ( x, y, z ) = x + ( ( x
```

Add WeChat edu\_assist\_pro

Solution: Use **frame pointer** `$fp`.

- ▶ Always points to the top of current AR as long as invocation is active.

## Code generation: frame pointer

```
def f ( x, y, z ) = x + ( ( x
```

Add WeChat edu\_assist\_pro

Solution: Use **frame pointer**  $\$fp$ .

- ▶ Always points to the top of current AR as long as invocation is active.
- ▶ The FP does not (appear to) move, so we can find all variables at a fixed offset from  $\$fp$ .

## Code generation: variable use

Let's compile  $x$  which is the  $i$ -th (starting to count from 1) parameter of `def f(x1, x2, ..., xn) = body` works like this (using offset in AR):

```
def genExp ( e : Exp ) =  
  if e is of form Variable ( x ) then
```

Assignment Project Exam Help

```
def genExp ( e : Exp ) =  
    if e is of form Variable ( x ) then
```

<https://eduassistpro.github.io>

Putting the arguments in reverse order on the offsetting calculation `val offset = 4`

Key insight: access at **fixed offset** r

changing pointer. Offset and pointer location are known at compile time.

This idea is pervasive in compilation.

## Code generation: variable use

In the declaration `def f(x, y, z) = ...`, we have:

<https://eduassistpro.github.io>

Third argument: 33

Second argument: 100

First argument: 7

Return address

Note th

indexi

and ar

stack from right to left.

Easy!

## Code generation: summary remarks

The code of variable access, procedure calls and declarations depends totally on the layout of the AR, so the AR must be designed together with the code generator, and all parts of the code generator must agree on AR conventions. It's just as important to be clear about the nature of the stack (grows upwards or downwards), frame pointer etc.

Another interesting observation: inefficiency of the translation

As already pointed out at the beginning of this course, stack- and accumulator machines are inefficient.

# Assignment Project Exam Help

<https://eduassistpro.github.io>

Add WeChat edu\_assist\_pr

## Another interesting observation: inefficiency of the translation

As already pointed out at the beginning of this course, stack- and accumulator machines are inefficient. Consider this from the previous slide (compilation of parts of  $n \neq 0$  in `sumt.c`):

```
lw $a0 4($fp)           // first we load n into the
```

k

<https://eduassistpro.github.io>

```
addiu $sp $sp -4
```

```
li $a0 0
```

```
lw $t1 4($sp)
```

```
           // now we load n back from
```

```
           // the sta
```

## Another interesting observation: inefficiency of the translation

As already pointed out at the beginning of this course, stack- and accumulator machines are inefficient. Consider this from the previous slide (compilation of parts of `n = 0` in `sumt.c`):

```
lw $a0 4($fp)           // first we load n into the
```

k

<https://eduassistpro.github.io>

```
addiu $sp $sp -4
```

```
li $a0 0
```

```
lw $t1 4($sp)           // now we load n back from  
                        // the sta
```

This is the price we pay for the simplicity of compilation strategy.

## Another interesting observation: inefficiency of the translation

As already pointed out at the beginning of this course, stack- and accumulator machines are inefficient. Consider this from the previous slide (compilation of parts of  $n \neq 0$  in `sumt.c`):

```
lw $a0 4($fp)          // first we load n into the
```

k

## Compiling whole programs

So far we have only compiled expressions and single declarations, but a program is a sequence of declarations, and it is called from, and returns to the OS. To compile a whole program we do the following.

- ▶ Creating the 'preamble', e.g. setting up data declarations,

- ▶ <https://eduassistpro.github.io>

Java's `main` – other languages might have conventions 'to get the ball rolling'. This involves

1. Creating (the caller's side of) an activation record.
2. Jump-and-link'ing to the first procedure.
3. Code that hands back control gracefully to the OS after program termination. Termination means doing a return to the place after (2). This part is highly OS specific.

## Compiling whole programs

Say we had a program declaring 4 procedures `f1`, `f2`, `f3`, and `f4` in this order. Then a fully formed compiler would typically generate code as follows.

**Assignment Project Exam Help**

```
prologue
